

## Daily Problem: 21–Jan–2026

### Problem Statement

Let  $M = (Q, \Sigma, \delta, q_0, F)$  be a DFA. Prove that  $L(M)$  is infinite if and only if the transition graph of  $M$  contains a directed cycle that is reachable from the start state and from which some accepting state is reachable (i.e., the cycle is both reachable and co-reachable).

### Proof

We prove both directions of the statement.

#### **( $\Rightarrow$ ) If such a cycle exists, then $L(M)$ is infinite**

Suppose there exists a state  $p \in Q$  such that:

- $p$  is reachable from  $q_0$ ,
- there is a nonempty string  $v$  with  $\delta(p, v) = p$  (so  $v$  forms a directed cycle at  $p$ ),
- some accepting state  $f \in F$  is reachable from  $p$ .

Let  $u$  be a string taking  $q_0$  to  $p$ , and let  $w$  be a string taking  $p$  to  $f$ . Then for every  $k \geq 0$ , the string

$$uv^kw$$

leads from  $q_0$  to  $p$ , loops around the cycle  $k$  times, and then reaches the accepting state  $f$ . Since all these strings are distinct (their lengths differ),  $L(M)$  contains infinitely many strings. Hence  $L(M)$  is infinite.

**( $\Leftarrow$ ) If  $L(M)$  is infinite, then such a cycle must exist**

Assume  $L(M)$  is infinite. Let  $|Q| = n$ . Because  $L(M)$  is infinite, there exists an accepted string  $x$  with length at least  $n$ . Consider the sequence of states the DFA enters while processing  $x$ :

$$q_0, q_1, q_2, \dots, q_{|x|}$$

where  $q_0$  is the start state and  $q_{|x|} \in F$ . This sequence has  $|x| + 1 \geq n + 1$  states but only  $n$  distinct possible states, so by the pigeonhole principle there exist indices  $0 \leq i < j \leq |x|$  such that

$$q_i = q_j.$$

Let the input  $x$  be written as  $x = abc$ , where:

- $a$  is the prefix taking  $q_0$  to  $q_i$ ,
- $b$  is the substring read from steps  $i + 1$  to  $j$ ,
- $c$  is the remainder of the input.

Since  $q_i = q_j$ , reading  $b$  from  $q_i$  returns to the same state, so  $b$  labels a directed cycle at  $q_i$ . Moreover, since  $x$  is accepted, reading  $c$  from  $q_i$  eventually reaches some accepting state. Thus:

- the cycle is reachable from  $q_0$  (via  $a$ ), and
- there is a path to an accepting state (via  $c$ ).

Hence a reachable and co-reachable cycle exists.

## Conclusion

We have shown both directions, so we conclude that:

$L(M)$  is infinite  $\iff$  the transition graph of  $M$  contains a reachable and co-reachable directed cycle
